Re: Comments on the Department's Labor Calculation Methodology

Dear Acting Assistant Secretary Spetrini:

These comments are filed on behalf of Grunfeld Desiderio Lebowitz Silverman & Klestadt, LLP ("GDLSK") in response to the U.S. Department of Commerce's request for comment on the NME labor calculation methodology, as published in 70 Fed. Reg. 37,761 (June 30, 2005).

An original and six copies of GDLSK's comments are attached. These comments were also submitted by email.

Please contact the undersigned if you or your staff has any questions regarding these comments.

Respectfully submitted,

Grunfeld Desiderio Lebowitz  
Silverman & Klestadt LLP

**ON**

**NME LABOR RATE CALCULATION  
METHODOLOGY**

**AUGUST 1, 2005**

**SUBMISSION OF GRUNFELD DESIDERIO  
LEBOWITZ SILVERMAN & KLESTADT,  
LLP (“GDLSK”)**

Grunfeld Desiderio Lebowitz Silverman & Klestadt LLP (“GDLSK”), hereby responds to the United States Department of Commerce’s (“Department” or “DOC”) request for comment on the NME labor rate calculation methodology, published in 70 Fed. Reg. 37,761 (June 30, 2005).

**Factual Background**

On June 30, 2005, the Department of Commerce published a request for comment on the nonmarket economy (“NME”) labor rate calculation methodology. While the Federal Register notice provides a summary of the calculation methodology in general, the Department failed to mention the impetus behind the request for comment. As such, we begin with the facts.

Pursuant to 19 C.F.R. 351.408(c)(3), Commerce determines the surrogate value for labor by using a regression-based analysis of the observed relationships between wages and national income in market economy countries to estimate wage rates for NME countries.<sup>1</sup> The regulation states, in its entirety:

*Labor.* For labor, the Secretary will use regression-based wage rates reflective of the observed relationship between wages and national income in market economy countries. The Secretary will calculate the wage rate to be applied in nonmarket economy proceedings each year. The calculation will be based on current data, and will be made available to the public.

19 C.F.R. 351.408(c)(3).

---

<sup>1</sup> Wage Rate = (NME country’s GNI per-capita \* X Coefficient) + Constant. See <http://ia.ita.doc.gov/wages/index.html>.

On October 6, 2004, the Department made its annual revision to the NME labor rate calculation and posted updated 2002 wage and Gross National Income (“GNI”) data.<sup>2</sup> That information was posted on the Department’s website at <http://ia.ita.doc.gov/wages/index.html>. The Department stated that the updated expected wage rate for China, based on the new 2002 information, was \$0.93/hour.

GDLSK argued in Wooden Bedroom Furniture from the PRC and Frozen and Canned Warmwater Shrimp from the PRC that this regression analysis labor calculation was improper because it relied on Chinese GNI data, which Commerce deems “unreliable” due to China’s non-market economy status. See Allied Pacific’s Case Brief at pp. 37-39 (Oct. 19, 2004). In addition, GDLSK noted that Commerce’s updated labor calculation contained calculation errors and that it did not appear to utilize all available 2002 wage rate and GNI information.<sup>3</sup> Id. GDLSK argued that, should the Department continue to value labor using its regression analysis based on wage rates and GNI for countries throughout the world, it must disclose additional information and correct specific errors in its calculation. Id. at 39-42. Finally, GDLSK noted that – simply using the countries Commerce acknowledged were included in its calculation – the 2002 data should have yielded a surrogate labor value for China of \$0.72 per hour rather than \$0.93. Id.

---

<sup>2</sup> GNI was previously known as GNP (Gross National Product).

<sup>3</sup> The Department had not disclosed documentation underlying the Department’s data points, it did not reveal the “X-Coefficient” or the “Constant” for the updated labor rate calculation as it had done in past-years’ updates, and most importantly, the 2002 wage data actually yielded an hourly rate of \$0.72/hour, not \$0.93/hour as stated by the Department. See Allied Pacific Case Brief, at 39-40. Allied Pacific provided Commerce with a worksheet displaying its correction of the Department’s error. See id. at Exhibit 6.

On approximately November 1, 2004, Commerce removed from its web site the back-up information for its original 2002 labor rate calculation. On November 15, 2004, Commerce released a revised 2002 wage rate calculation. However, this revised calculation removed the 2002 wage rate data and replaced it with the 2001 data from the previous year. The Department continued to reach the \$0.93/hour wage rate for China by combining 2001 wage rate data and 2001 per-capita GNI data with 2002 GNI data for China. See Commerce's Notes on its surrogate wage rate calculation at <http://ia.ita.doc.gov/wages/index.html>. The Department mixed 2001 and 2002 data despite the fact that 2002 data was readily available. Commerce had never previously mixed data from separate years, and it provided no explanation for this deviation in its methodology.

In notes accompanying its revised labor rate calculation, Commerce stated that it relied on wages reported in the Yearbook of Labor Statistics 2002 (Chapter 5B), published by the ILO, which includes wage rates from 1996-2001. Id. Per-capita GNI for 2001 for market economy countries was taken from the 2003 World Development Indicators, and per-capita 2002 GNI for China was taken from the 2004 World Development Indicators, published by the World Bank. Id. However, Commerce failed to mention that 2002 per-capita GNI data was available from the 2004 World Development Indicators, and 2002 wage data was available from the Yearbook of Labor Statistics 2003 or the ILO's website.<sup>4</sup> Thus, the very same sources Commerce used for its hybrid 2001/2002 calculation would have enabled Commerce to perform the calculation based solely on the more current 2002 data, as it had originally claimed to do.

---

<sup>4</sup> Wages by country for Chapter 5B (manufacturing wages) are available on-line at the ILO's website, at <http://laborsta.ilo.org/>.

In its Final Determination in both Furniture and Shrimp, the Department explained that it needed more time “to determine an accurate construction of a new dataset and to conduct a new regression analysis.” Id. at 18. However, Commerce did not explain why it required more time to review this particular calculation, and it did not state how much time would be required.

The Department’s labor calculation was appealed to the Court of International Trade in both the Furniture and Shrimp cases. In both cases, the Department consented to a remand on this issue, stating “[u]pon further review of this issue, it appears that Commerce’s calculation of the labor wage rate may be erroneous and in need of recalculation.” Allied Pacific v. United States, Court No. 05-00056; See also, Dorbest Ltd., Rui Feng Woodwork (Dongguan) Co., v. United States, Court No. 05-0003; citing SKF v. United States, 254 F. 3d 1022 (Fed. Cir. 2001) (a remand is appropriate when the agency has doubts about the correctness of its decision.).<sup>5</sup>

Finally, on June 30, 2005, the Department published a request for comment on the wage calculation methodology. The request, however, makes no mention of its errors in the calculation of the 2002 Chinese labor rate. Instead, the request gives background information about how the wage calculation is made in general and proposes new NME wages for 2003.

---

<sup>5</sup> Despite requesting a remand in these appeals and acknowledging errors in its calculation, the Department has continued to use the “revised” 2002 labor calculation based on the 2001 data in each Chinese case since Furniture, including the final results of Administrative reviews.

## Proposed Modifications

### **The Department's 2003 Wage Rate Calculation Should Include All Available Data**

The Department's proposed 2003 wage rate calculation remains flawed because it does not use all available wage and GNI information.

As discussed above, Commerce states on its website that it obtains country-wide labor rates from the Yearbook of Labor Statistics, and that it obtains per capita GNI data from World Development Indicators. See Commerce's Notes regarding its regression based labor calculation at <http://ia.ita.gov/wages.html>. The 2003 data set used in Commerce's calculations contain per-capita GNI and wage data from 52 market economy countries.<sup>6</sup> Id. However, the Yearbook of Labor Statistics and the World Development Indicators include per-capita GNI and wage data for numerous other countries that Commerce did not use in its calculation. In fact, these two sources contain the necessary information meeting the Department's criteria for 66 countries.<sup>7</sup> Commerce, however, inexplicably ignored the available 2003 data from 14 of the 66 countries.<sup>8</sup>

Commerce has offered no explanation for the exclusion of this available data from these additional 14 countries, and its omission directly conflicts with Commerce's justification for adopting the regression based calculation. When adopting its regulation

---

<sup>6</sup> For the 2003 calculation, the Department dropped the Dominican Republic, Algeria and Kenya because ILO wage rate data were not available for these countries in the instant dataset. Commerce also dropped Zimbabwe because 2003 GNI data were not available.

<sup>7</sup> The Department requires that each country's wage data is no more than 6 years old. The Department also requires that each country has available a consumer price index. See Request for Comment on Calculation Methodology, 70 Fed. Reg. 37761 (June 30, 2005).

<sup>8</sup> Per capita GNI and wage data from the past six years were also available for the following countries that Commerce did not use in its calculation: Albania, Cambodia, Czech Republic, Denmark, Hungary, Indonesia, Iran, Kazakhstan, Kuwait, Latvia, Macedonia, Mongolia, Slovakia and Uruguay.

for use of a regression based wage rate, the Department stated, “we believe that more data is better than less data” and “the regression-based approach will yield a more accurate result” because it relies on multiple countries. Notice of Final Rule Making, 62 Fed. Reg. at 27,367. Clearly if more data is better than less data the Department should use the information from the 14 other countries whose data is available from the same sources.

In addition, it is widely accepted that the omission of available data in a regression analysis results in biased and distorted results. See, e.g., JAN KMENTA, ELEMENTS OF ECONOMETRICS at 341-344 (1971). See also, Report of Daniel W. Klett, included as **Exhibit 1** to this letter; Report of Dr. Tapan K. Nayak, included as **Exhibit 2**. Thus, the exclusion of data from certain countries cannot be reconciled with Commerce’s use of a regression-based calculation. This fact is especially pertinent in the instant case since Commerce’s methodology purports to calculate a “worldwide” relationship between wages and GNI. The calculation cannot be said to be “worldwide” if 14 out of the 66 countries whose data is published in the sources used by the Department are omitted without justification.

Furthermore, the Department’s error cannot be explained away by arguing that its choice of 52 countries is a random sampling. First, in any random sampling, “standard errors decrease as sample size increases.” Report of Dr. Tapan K. Nayak, included as **Exhibit 2**. As such, using the data from 66 countries would lead to more accurate results than using 52 countries. Second, record evidence indicates that the 14 countries the Department disregarded were not excluded randomly because these countries have been disregarded without explanation in prior years as well. See

<http://ia.ita.doc.gov/wages/index.html>. Third, there is no need to sample at all in this situation because the total amount of available data consists of only 66 countries.

Including these 14 countries would not result in any additional burden to the Department and would result in a more representative wage rate. See, e.g., Report of Dr. Tapan K. Nayak, in **Exhibit 2**.

In addition, this error in Commerce's calculation calls into question the validity of the reasoning Commerce used when adopting this regression based methodology in the first place. As discussed above, Commerce asserted that the regression-based labor calculation was valid (despite the fact that it appeared to violate the statute's requirements for surrogate country sources that were economically comparable and significant producers of comparable merchandise) because it promoted accuracy, fairness and predictability. Notice of Final Rule Making, 62 Fed. Reg. at 27,367. However, if Commerce is free to cherry-pick a subset of available data and thereby distort the resulting calculation without even informing the public of this irregularity, then this methodology cannot be promoting accuracy, fairness or predictability. Furthermore, it is not performing a true regression based analysis in a representative manner.

For the above reasons, if Commerce continues using a regression-based labor calculation, it should revise its 2003 calculation to include all market economy countries for which a) per-capita GNI data for 2003 is available from the 2005 World Development Indicators, and b) wage data is available from the ILO's Yearbook of Labor Statistics 2004 for any year between 1998 and 2003.

# **Exhibit 1**

Report of Daniel W. Klett, Principal  
Capital Trade, Incorporated

Department of Commerce NME Wage Methodology

I. Introduction

I have been retained by Grunfeld Desiderio to provide an opinion on the statistical reliability of the most recent regression-based methodology used by the Department of Commerce ("Commerce") to value non-market-economy (NME) wage rates. My background is included as Attachment 1 to this report.

Pursuant to 19 CFR 351.408(c)(3), the Department relies on regression analysis of the observed relationships between wages and national income in market economy countries to estimate wage rates for non-market economy countries in antidumping duty investigations. This regulation also states that "The calculation will be based on current data, and will be made available to the public." In its response to comments on this proposed change to its methodology for valuing NME wage rates, the Department stated that "In general, we believe that more data is better than less data, and that averaging of multiple data points (or regression analysis) should lead to more accurate results in valuing any factor of production."<sup>1</sup>

The most recent estimates by Commerce for NME wages is based on a regression of market economy 2001 wages and per capita Gross National Income (GNI), the results of which are applied to 2002 per capita GNI for NMEs to estimate NME wages.<sup>2</sup> Previous estimates relied on contemporaneous years for both market economy and NME data.<sup>3</sup>

There are two issues addressed below regarding the methodology for the current estimates of NME wages. First, why is Commerce relying on 2001 market economy data

---

<sup>1</sup> 62 FR 27367 (May 19, 1997).

<sup>2</sup> See Attachment 2, a PDF version of the November 15, 2004 updates of NME wages for 2002.

<sup>3</sup> See <http://ia.ita.doc.gov/wages/index.html>, accessed on January 3, 2005.

when more current data are available, and is it appropriate to apply the regression results from 2001 market economy data to 2002 NME GNI data? Second, why are datapoints from some market economies for which data are available excluded from the regression analysis, and what does this mean for the reliability of the statistical results?

## II. Reliance on Non-Current 2001 Market Economy Data

In notes supporting its calculations, Commerce reports that it has relied on wages reported in the Yearbook of Labour Statistics 2002 (Chapter 5B), published by the ILO. It states that it included reported wage rates for the years 1996 to 2001. Data for years prior to 2001 are inflated to 2001 based on consumer price indices of the International Financial Statistics Online Service. Per capita GNI for 2001 for market economy countries was from the 2003 World Development Indicators, and per capita 2002 GNI for NMEs was from the 2004 World Development Indicators, published by the World Bank.<sup>4</sup>

Commerce provides no rationale for why it has relied on 2001 data for the market economy regression, when data are available for 2002 per capita GNI from the 2004 World Development Indicators, and for many countries 2002 wages from the Yearbook of Labour Statistics 2003 or the ILO's website.<sup>5</sup> This runs counter to the Department's own regulations that the annual re-calculation of the wage rate be based on "current data." Furthermore, application of the 2001 market-economy regression results to 2002 NME per capita GNI is an apples-to-oranges comparison that departs (with no explanation given since 2002 market economy data are available) from how NME wages were estimated in

---

<sup>4</sup> See Attachment 2.

<sup>5</sup> See Attachment 3 Table 1.1 from the World Development Indicators. Commerce did present 2002 data for market economy wages and per capita GNI in a prior estimate on its website posted in October 2004, but these data were withdrawn after a critique by respondents in the investigation involving furniture from China which could not replicate the Commerce results. Wages by country for Chapter 5B (manufacturing wages) are available on-line at the ILO's website, at <http://laborsta.ilo.org/>. Data from this source is included in Attachment 4, which has been modified to exclude lines other than "total" wages.

prior periods. As shown in the tabulation below, the regression based results can vary considerably from year-to-year:

Period	Constant	Coefficient 1/
1995	.3705	.000516
1997	.3715	.000475
1998 2/	.4540	.000464
1999	.3981	.000475
2000	.4622	.000432
2001	.5123	.000437
2002 (used) 3/	.5123	.000437
2002 (actual) 4/	.3620	.000504

1/ applied to per-capita GNP or GNI.

2/ Commerce inexplicably dropped Denmark from the market economy countries for this period, although it had been included in previous regressions.

3/ Based on regression of 2001 market economy data, applied to 2002 NME per-capita GNI. See Attachment 2.

4/ Based on regression of 2002 market economy data for same set of countries as for 2001 regression. However, per capita GNI data for the Dominican Republic was not reported by the World Bank for 2002, so this country is omitted. (See Attachment 5 for data support, and Attachment 6 for results).

As shown in the above tabulation, a regression using the same set of market economy countries as in 2001, but using current 2002 data, yields significantly different results. The Department's arbitrary decision to use less contemporaneous data when more current data is available runs counter to the stated reasons for adopting the regression-based approach as being "fair," and "entirely predictable." It should be noted that predictability in this regard is not with respect to the results, but with respect to a consistent method.

Finally, for some countries, Commerce has relied on dated wage data from the ILO's hard copy 2002 Yearbook, (with the data inflated to 2001), even though actual wage data for later years is available from the on-line database from this same source.<sup>6</sup> In this regard, there is no reason to rely on the hard-copy ILO publication, when more current data

<sup>6</sup> For example, among the countries for which 2002 data are available on-line, but not in the most recent hard-copy publication (2003 Yearbook) are Botswana, Brazil, Chile, Mexico, and the United States. This list is not all-inclusive.

are available from this same source on the ILO website. Reliance on the website data will not result in Commerce continuously having to update its estimates when/if more current data are made available on-line, since it is clear that its estimates are re-calculated only on an annual basis. There is no reason to not rely on the most up-to-date data available when the estimates are made, particularly give the Department's regulations that the estimates be based on "current" data. The online data is available to all potential respondents around the world who have internet access, thereby allowing respondents to have access to the same data as the DOC, thereby enabling them to better predict the annual wage rate calculation.

III. Commerce Has Arbitrarily Selected a Subset of Market Economy Data, Which Distorts its Results and Undercuts the Representativeness of the DOC's Calculated Worldwide Relationship Between Wages and GNI

In its notes to its NME wage rate calculations for 2002, Commerce states that "the selection of countries was based upon the availability of wage data as reported in the Yearbook of Labor Statistics 2002." The notes also state that countries reporting wages for the years 1996 to 2001 are included in the analysis. In its latest calculation, Commerce relied on per-capita GNI and wage data from 56 market economy countries.<sup>7</sup> However, there are a significant number of market economy countries that were excluded from the analysis, where per-capita GNI was available from the World Development Indicators and manufacturing wage data were available from the ILO. These countries are:

Albania	Iran	Saudi Arabia
Bangladesh	Kazakstan*	Serbia & Montenegro
Cambodia	Kuwait	Slovakia
Czech Republic	Latvia	Swaziland

<sup>7</sup> See Attachment 2. The notes indicate that it used countries where data were available from 1996 to the year at issue. Where the most recent wages were for a year prior to that for which the regression was applied, the wages were inflated based on consumer price indices. As discussed in the section above, there is no basis for relying on the 2002 Yearbook of Labour Statistics when more current data are available from the 2003 Yearbook, and on the ILO's website.

Denmark	Macedonia	Uruguay
Gambia	Mongolia	Venezuela
Hungary	Portugal	
Indonesia	Rwanda	

\* Kazakstan received market economy status in 2001 so should be in the list of market economy countries for a 2002 regression-based analysis of wages.

There is no reason why data from these countries should be excluded, given Commerce's position that "more data is better than less data" when supporting its use of the regression-based methodology.<sup>8</sup> Furthermore, the exclusion of these datapoints from the analysis seriously undermines the reliability of the results for statistical reasons. It is well known that the results of a regression with missing values is biased.<sup>9</sup> In fact, the distortion can be confirmed by evaluating the results with and without data from these 22 countries, as shown in the following tabulation (based on 2002 market economy wage and per capita GNI data):<sup>10</sup>

	Constant	GNI Coefficient
55 Countries <sup>11</sup>	.362	.000504
77 Countries	.045	.000533

Since the DOC's methodology purports to calculate a worldwide relationship between wages and GNI, using only a subset of countries for which data is available does not yield a representative relationship. As demonstrated above, using the 2002 wage and GNI data from the countries selected by the DOC versus all countries for which data are available yields a different result. Thus, the Department's use of only a subset of the countries for which data are available does not yield a correlation between wage and GNI for all countries for which data is available. Any resulting estimated surrogate wage rate

<sup>8</sup> 62 FR 27367 (May 19, 1997).

<sup>9</sup> See, e.g., *Elements of Econometric*, Jan Kmenta, 1971, at 341-344 (see Attachment 7).

<sup>10</sup> See Attachment 5 for data and Attachment 6 for results.

<sup>11</sup> There is no 2002 per capita GNI data available for the Dominican Republic in the most recent World Development Report, which is why we include only 55 of the 56 countries that the Department used based on 2001 data.

using the results of a regression calculation based on only a subset of available datapoints is therefore based on a statistically unrepresentative calculation.

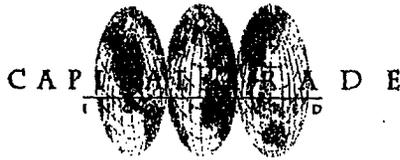

IV. Conclusion

For the above reasons, Commerce should revise its 2002 wage rates for NME's based on using 2002 per capita GNI data from the 2004 World Development Indicators, and the most current wage rate data from the ILO (hard copy and on-line), inflated to 2002 when necessary. Commerce should also include in its regression-based wage analysis all market economy countries for which: a) per capita GNI data for 2002 is available from the World Development Indicators, and b) wage data is available from the ILO for any year between 1996 and 2002.

## **EDUCATION**

1985, M.A., Economics, Georgetown University  
1976, B.A., Economics, College of the Holy Cross

## **EXPERIENCE**

Mr. Klett is a principal with Capital Trade, Incorporated. His background is in international economics and trade regulation, with specific expertise in assessing the economic impact of imports on U.S. industries and consumers. He has participated in studies involving U.S. export control regulations, direct foreign investment in the United States, and financial analysis of the member companies of an international consortium.

### **Economic Analysis**

Mr. Klett's experience in economic analysis of international trade issues includes:

- Analysis of impact of imports on competing U.S. industry, including use of existing economic models, econometric analysis of time series data, and testimony
- Estimation of impact of trade restrictions on consumers
- Economic analysis relating to domestic industry issues in Section 337 investigations at the U.S. International Trade Commission, and expert testimony
- Statistical analysis to support arguments made to the Department of Commerce in antidumping investigations

### **Case Experience - U.S. International Trade Commission:**

- Framing Stock from the UK
- Softwood Lumber from Canada
- Uranium
- Flat Panel Displays from Japan
- Cement (Japan, Mexico, Venezuela)
- Industrial Nitrocellulose
- Atlantic Salmon from Norway
- Silicon Metal from Brazil
- Aspheric Ophthalmoscopy Lenses from Japan
- Honey from China
- Pencils from China
- Bulk Diltiazem (Section 337)

DANIEL W. KLETT

Page 2

**Case Experience - U.S. International Trade Commission (cont.):**

- Polyvinyl Alcohol (Japan, Korea, Taiwan, PRC)
- Salinomycin Biomass (Section 337)
- Rebar from Turkey
- Pasta from Italy and Turkey
- Stainless Steel Wire Rod
- Wheat Gluten (Section 201)
- EEPROMs (Section 337)
- Titanium Sponge (Changed Circumstance Review)
- Cut-to-Length Carbon Steel Plate
- Ferrosilicon (Changed Circumstance Review)
- Roller Chains from Japan (Sunset Review)
- Color Picture Tubes (Sunset Review)
- Silicon Metal (Sunset Review)
- Various carbon steel products
- Table Grapes from Chile
- Steel Wire Rope
- Ammonium Nitrate (Russia, Ukraine)
- Large Diameter Line Pipe
- Low-Enriched Uranium
- Automotive Replacement Glass from China
- Oil Country Tubular Goods
- DRAMs from Korea
- Urea Ammonium Nitrate
- Shrimp
- Outboard Motors from Japan

**Case Experience - U.S. Department of Commerce:**

- Industrial Nitrocellulose from Seven Countries
- Atlantic Salmon from Norway
- Kiwifruit from New Zealand
- Man-Made Fiber Sweaters from Korea
- Potassium Permanganate from Spain and China
- Aspheric Ophthalmoscopy Lenses from Japan
- Flat-Rolled Carbon Steel Products from various countries
- Oil Country Tubular Goods from various countries
- Stainless Steel Bar from India
- Sebacic Acid from China

DANIEL W. KLETT

Page 3

### Other Projects

Mr. Klett has participated in other international trade-related projects, including:

- Consumer cost study for Japanese semiconductor companies involved in an EC antidumping proceeding.
- Analysis of the impact of U.S. national security export controls on the international business strategies of U.S. high-technology companies.
- Assistance to a Swiss manufacturer in assessing the feasibility of setting up manufacturing facilities in the United States, and site location.
- Analysis of the financial condition of Airbus members, in the context of state support and commercial conditions.
- Section 301 investigation involving modified wheat starch from the EU (on behalf of EU grain industry).

### Prior Experience

Prior to forming Capital Trade, Incorporated, Mr. Klett was a Vice President with ICF Consulting Associates (1990-92), and a supervisor at Coopers & Lybrand (1987-90).

From 1979 to 1987, Mr. Klett was an economist at the U.S. International Trade Commission, first in the Office of Economics (1979-1986) and then as the economic advisor to four Administrative Law Judges (1986-1987) involved in Section 337 proceedings.

From 1977 to 1979, Mr. Klett served as a Peace Corps volunteer in Sierra Leone, teaching economics at the high school junior to introductory university levels.

NOTES

EXPECTED 2002 WAGES OF SELECTED NME COUNTRIES		
Armenia	\$790	\$0.86
Azerbaijan	\$710	\$0.82
Belarus	\$1,360	\$1.11
Estonia	\$4,190	\$2.34
Georgia	\$650	\$0.80
Kazakhstan	\$1,520	\$1.18
Kyrgyz Republic	\$290	\$0.64
Lithuania	\$3,670	\$2.12
Moldova	\$460	\$0.71
People's Republic of China	\$960	\$0.93
Romania	\$1,870	\$1.33
Russian Federation	\$2,130	\$1.44
Tajikistan	\$180	\$0.59
Turkmenistan	\$950	\$0.83

2002 INCOME DATA - EXPECTED WAGES OF SELECTED NON-MARKET ECONOMY COUNTRIES

Ukraine	\$780	\$0.85
Uzbekistan	\$310	\$0.65
Vietnam * *	\$430	\$0.70
Wage Rate = GNP * 0.000437 + 0.512269		

\* Applicable only to review periods that pre-date the effective date of graduation to market-economy status (Estonia (01/01/03); Lithuania (01/01/03); Romania (01/01/03); and Russia (04/01/02); Kazakhstan (10/01/01)).

\* \* On November 8, 2002, the Department determined that Vietnam will be treated as a non-market economy country for purposes of antidumping duty and countervailing proceedings (see Memorandum for Faryar Shirzad, Antidumping Duty Investigation of Certain Frozen Fish Fillets from the Socialist Republic of Vietnam—Determination of Market Economy Status (A-552-801)).

Wage Rate = GNP * 0.000437 + .512269			

**Notes:****General:**

The selection of countries was based upon the availability of wage data as reported in the Yearbook of Labour Statistics 2002, International Labour Organisation, (Geneva: 2002); and GNI data as reported in World Development Indicators, The World Bank, (Washington, DC: 2003 and 2004).

**Wages:**

Wage rates are reported in the Yearbook of Labour Statistics 2002, ILO, (Geneva: 2002), Chapter 5B: Wages in Manufacturing. The years of the reported wage rates range from 1996 to 2001. Wages reported prior to 1996 and after 2002 are excluded from the analysis.

Wages reported by ILO are in most cases based on cash payments received from employers on a regular basis. In addition to remuneration for normal working hours, cost-of-living allowances and other regularly paid allowances are included in wages. Wages do not include remuneration for overtime, bonuses and gratuities, family allowances, or other social security payments made by the employer. See Yearbook of Labour Statistics 2002 for further discussion of wage data.

Where monthly or daily wages are given, hourly wages are calculated assuming 24 working days per month, 5.5 working days per week, 8 working hours per day.

**Inflator:**

Wages are inflated, where the base year is not 2001, using consumer price index data reported in International Financial Statistics Online Service, International Monetary Fund, (<http://www.imf.org>). The inflator rate is calculated by dividing the consumer price index for 2001 by the consumer price index for the year the wage rate was reported.

**Exchange rates:**

Exchange rates are expressed as foreign currency per one U.S. dollar. For the majority of the countries in this analysis, the exchange rates used are as reported in International Financial Statistics Online Service.

Since exchange rates were not available in the International Financial Statistics for Austria, Belgium, Finland, France, Germany, Greece, Ireland, Netherlands, and Spain, the Department relied on the exchange rate information which it regularly obtains from Dow Jones B.I.S. and the Federal Reserve and posts on the Import Administration web site for these countries. The exchange rates used are 2001 market averages.

**National Income:**

GNI per capita is reported in World Development Indicators, The World Bank, (Washington, DC: 2003 and 2004). For its regression analysis, the Department used GNI per capita figures from the 2003 publication. For its calculation of expected NME wages, the Department used GNI per capita figures from the 2004 publication. See World Development Indicators for further information.

GNI data was not available in the World Development Indicators for Nicaragua for 2001. Therefore, we used GNI data from the International Financial Statistics. We derived the per capita GNI from the population data included in this source.

**Analysis:**

Regression based on ordinary least squares method.

a. PPP is purchasing power parity; see Definitions. b. Calculated using the World Bank Atlas method. c. Estimate does not account for recent refugee flows. d. Estimated to be low income (\$735 or less). e. The estimate is based on regression; others are extrapolated from the latest International Comparison Programme benchmark estimates. f. Includes Taiwan, China; Macao, China; and Hong Kong, China. g. Estimate based on bilateral comparison between China and the United States (Ruon and Kai, 1995). h. Estimated to be lower middle income (\$736-\$2,935). i. GNI and GNI per capita estimates include the French overseas departments of French Guiana, Guadeloupe, Martinique, and Réunion. j. Estimated to be upper middle income (\$2,936-\$9,075). k. Estimated to be high income (\$9,076 or more). l. Excludes data for Kosovo. m. Data refer to mainland Tanzania only.

## About the data

Population, land area, income, and output are basic measures of the size of an economy. They also provide a broad indication of actual and potential resources. Population, land area, income—as measured by gross national income (GNI)—and output—as measured by gross domestic product (GDP)—are therefore used throughout *World Development Indicators* to normalize other indicators.

Population estimates are generally based on extrapolations from the most recent national census. For further discussion of the measurement of population and population growth, see *About the data* for table 2.1 and *Statistical methods*.

The surface area of a country or economy includes inland bodies of water and some coastal waterways. Surface area thus differs from land area, which excludes bodies of water, and from gross area, which may include offshore territorial waters. Land area is particularly important for understanding the agricultural capacity of an economy and the effects of human activity on the environment. (For measures of land area and data on rural population density, land use, and agricultural productivity, see tables 3.1–3.3.) Recent innovations in satellite mapping techniques and computer databases have resulted in more precise measurements of land and water areas.

GNI (or gross national product in the terminology of the 1968 United Nations System of National Accounts) measures the total domestic and foreign value added claimed by residents. GNI comprises GDP plus net receipts of primary income (compensation of employees and property income) from non-resident sources.

The World Bank uses GNI per capita in U.S. dollars to classify countries for analytical purposes and to determine borrowing eligibility. See the *Users guide* for definitions of the income groups used in *World Development Indicators*. For further discussion of the usefulness of national income as a measure of productivity or welfare, see *About the data* for tables 4.1 and 4.2.

When calculating GNI in U.S. dollars from GNI reported in national currencies, the World Bank follows its *Atlas* conversion method. This involves using a three-year average of exchange rates to smooth the effects of transitory exchange rate fluctuations. (For further discussion of the *Atlas* method, see *Statistical methods*.) Note that growth rates are calculated from data in constant prices and national currency units, not from the *Atlas* estimates.

Because exchange rates do not always reflect international differences in relative prices, this table also

shows GNI and GNI per capita estimates converted into international dollars using purchasing power parity (PPP) rates. PPP rates provide a standard measure allowing comparison of real price levels between countries, just as conventional price indexes allow comparison of real values over time. The PPP conversion factors used here are derived from price surveys covering 118 countries conducted by the International Comparison Program. For Organisation for Economic Co-operation and Development (OECD) countries data come from the most recent round of surveys, completed in 1999; the rest are either from the 1996 survey, or data from the 1993 or earlier round and extrapolated to the 1996 benchmark. Estimates for countries not included in the surveys are derived from statistical models using available data.

All economies shown in *World Development Indicators* are ranked by size, including those that appear in table 1.6. The ranks are shown only in table 1.1. (*World Bank Atlas* includes a table comparing the GNI per capita rankings based on the *Atlas* method with those based on the PPP method for all economies with available data.) No rank is shown for economies for which numerical estimates of GNI per capita are not published. Economies with missing data are included in the ranking process at their approximate level, so that the relative order of other economies remains consistent. Where available, rankings for small economies are shown in *World Bank Atlas*.

Growth in GDP and growth in GDP per capita are based on GDP measured in constant prices. Growth in GDP is considered a broad measure of the growth of an economy, as GDP in constant prices can be estimated by measuring the total quantity of goods and services produced in a period, valuing them at an agreed set of base year prices, and subtracting the cost of intermediate inputs, also in constant prices. For further discussion of the measurement of economic growth, see *About the data* for table 4.1.

## Definitions

• **Population** is based on the de facto definition of population, which counts all residents regardless of legal status or citizenship—except for refugees not permanently settled in the country of asylum, who are generally considered part of the population of their country of origin. The values shown are midyear estimates for 2002. See also table 2.1. • **Surface area** is a country's total area, including areas under inland bodies of water and some coastal waterways. • **Population density** is midyear population divided by land area in square kilometers. • **Gross national income (GNI)** is the sum of value added by all resident producers plus any product taxes (less subsidies) not included in the valuation of output plus net receipts of primary income (compensation of employees and property income) from abroad. Data are in current U.S. dollars converted using the World Bank *Atlas* method (see *Statistical methods*). • **GNI per capita** is gross national income divided by midyear population. GNI per capita in U.S. dollars is converted using the World Bank *Atlas* method. • **PPP GNI** is gross national income converted to international dollars using purchasing power parity rates. An international dollar has the same purchasing power over GNI as a U.S. dollar has in the United States. • **Gross domestic product (GDP)** is the sum of value added by all resident producers plus any product taxes (less subsidies) not included in the valuation of output. Growth is calculated from constant price GDP data in local currency. • **GDP per capita** is gross domestic product divided by midyear population.

## Data sources

Population estimates are prepared by World Bank staff from a variety of sources (see *Data sources* for table 2.1). The data on surface and land area are from the Food and Agriculture Organization (see *Data sources* for table 3.1). GNI, GNI per capita, GDP growth, and GDP per capita growth are estimated by World Bank staff based on national accounts data collected by Bank staff during economic missions or reported by national statistical offices to other international organizations such as the OECD. Purchasing power parity conversion factors are estimates by World Bank staff based on data collected by the International Comparison Program.

Sources: Wages, measuring currency, unit, and reporting year from ILO, Chapter 5B, on-line database, at <http://laborsta.ilo.org/>

Inflators are based on consumer price indices from the International Monetary Fund (see attached calculations)

Exchange rates from the CIA World Factbook (see attached).

Countries in **bold Italics** are those not included by the Department in its most recent calculation of NME wages for which both wage and per capita GNI data are available.

pairs of observations. This can be done by substituting  $\hat{\xi}_1$  for the missing values of  $X$  in (9.46a). The result is

$$(9.48) \quad \text{Est. } \left[ \frac{\text{Var}(\beta_2)}{\text{Var}(\beta_1)} \right] = 1 + \frac{\sum (\hat{\xi}_1 - \bar{\xi})^2 + (n_2 m_2 / n) (\bar{X}_x - \bar{\xi})^2}{\sum (X_i - \bar{X}_x)^2}$$

The estimator  $\hat{\xi}_1$  has the desirable asymptotic properties possessed by other maximum likelihood estimators, provided the number of missing values of  $X$  does not grow with sample size.

**EXAMPLES** In the example in Section 7-3, we were concerned with estimating the coefficients of a linear relation between price ( $X$ ) and quantity or oranges sold ( $Y$ ) in a given supermarket over twelve consecutive days. The observations were:

$X$ :	100	90	80	70	70	70	65	60	60	55	50
$Y$ :	55	70	90	100	90	105	80	110	125	115	130

The results of the relevant calculations were as follows:

$$\begin{aligned} \bar{X} &= 70, \\ \sum (X_i - \bar{X})^2 &= 2250, \\ \hat{\alpha} &= 210.460, \\ \hat{\beta} &= -1.578. \end{aligned}$$

Suppose now that, in addition to the 12 pairs of observations, we also had the information that the quantity sold on the thirteenth day was 37 pounds but that no price has been reported. That is,  $Y_{13} = 37$ . This observation has been discarded. We wish to know how much efficiency we would have gained in estimating  $\beta$  if  $X_{13}$  had been known. First, we use (9.47) to estimate  $X_{13}$  as

$$\hat{\xi}_{13} = \frac{Y_{13} - \hat{\alpha}}{\hat{\beta}} = \frac{37 - 210.460}{-1.578} = 110.$$

Then, the estimated ratio of  $\text{Var}(\beta_2)$  to  $\text{Var}(\beta_1)$  is

$$1 + \frac{0 + [(12 \times 1) / 13] (70 - 110)^2}{2250} = 1.6564,$$

which means that the loss of efficiency is estimated to be 65.64%.

An alternative way of using the information contained in the incomplete pairs of observations is to fill in the gaps by using some approximations of the missing values of  $X$ . This approach is probably fairly common in practice. The approximations are obtained by, e.g., interpolation from the observed values of  $X$ , or by reference to some other variable  $Z$  that is correlated with  $X$ . However, if we replace the missing values of  $X$  with some approximations, we introduce errors

of measurement into the values of the explanatory variable and, as a consequence, obtain inconsistent estimates of the regression coefficients. This was explained in detail in Section 9-1. How serious this inconsistency will be depends, of course, on the extent of the errors of approximation. In fact, what is being done in this case is giving up consistency in the hope of reducing the variance of the estimator. If we are reasonably certain that the errors of approximation are small while the gain in efficiency is potentially large, this may be a rational procedure. Otherwise, the trade may result in a loss.

**Stochastic Explanatory Variable**

Let us now turn to the case where  $X$  is a stochastic variable that is distributed independently of the disturbance. The formulas for the least squares estimators of the regression coefficients based on complete pairs of observations remain unchanged, and so do the formulas for their variances—except that the latter have to be interpreted as conditional upon the given set of available values of  $X$ . Each pair of the observed values of  $X$  and  $Y$  now comes from a bivariate probability distribution. Our problem is to estimate the regression coefficients when some of the pairs of observations are incomplete. Other than disregarding the incomplete pairs, we may try to fill in the gaps and then apply the least squares estimation. One way of filling the gaps is to ask which value of  $X$ , or of  $Y$ , would one expect to observe before making the observation. Commonly, this would be the mathematical expectation of  $X$  or of  $Y$ , i.e., their means. Since the means are unknown, we can use the available sample means as estimators. That is, we may complete the missing observations in the incomplete pairs by using the available sample means of the respective variables. The least squares estimators of  $\alpha$  and  $\beta$  obtained from the sample completed in this way are called *zero order regression estimators*.<sup>7</sup> They are defined as follows:

$$(9.49) \quad \hat{\beta}_0 = \frac{\sum (X_1 - \bar{X}_x)(Y_1 - Y_p) + \sum \frac{(\bar{X}_x - \bar{X}_x)(Y_1 - Y_p)}{n_x} + \sum \frac{(X_1 - \bar{X}_x)^2}{n_x}}{\sum (X_1 - \bar{X}_x)^2 + \sum \frac{(\bar{X}_x - \bar{X}_x)^2}{n_x} + \sum \frac{(X_1 - \bar{X}_x)^2}{n_x}} + \frac{\sum (X_1 - \bar{X}_x)(Y_p - Y_p)}{\sum (X_1 - \bar{X}_x)^2 + \sum \frac{(\bar{X}_x - \bar{X}_x)^2}{n_x} + \sum \frac{(X_1 - \bar{X}_x)^2}{n_x}} = \frac{\sum (X_1 - \bar{X}_x)(Y_1 - Y_p)}{\sum (X_1 - \bar{X}_x)^2}$$

and

$$(9.50) \quad \hat{\alpha}_0 = Y_p - \hat{\beta}_0 \bar{X}_x.$$

<sup>7</sup> See A. A. Aftab and R. M. Elashoff, "Missing Observations in Multivariate Statistics II. Point Estimation in Simple Linear Regression," *Journal of the American Statistical Association*, Vol. 62, March 1967, pp. 10-29.

In order to see whether these estimators are unbiased, we substitute

$$Y_i - Y_y = \beta(X_i - X_y) + (\alpha - \bar{\alpha}_y)$$

into (9.49) to get

$$\hat{\beta}_0 = \frac{\sum_c (X_i - X_y)[\beta(X_i - X_y) + (\alpha - \bar{\alpha}_y)]}{\sum_c (X_i - X_y)^2}$$

The mathematical expectation of  $\hat{\beta}_0$ , conditional upon the observed values of  $X_i$ , is

$$E(\hat{\beta}_0) = \frac{\beta \sum_c (X_i - X_y + \bar{X}_c - \bar{X}_y)[X_i - X_y + \bar{X}_c - \bar{X}_y] + (\alpha - \bar{\alpha}_y) \sum_c (X_i - X_y)^2}{\sum_c (X_i - X_y)^2}$$

$$= \frac{\beta \sum_c (X_i - X_y)^2 + n_c(\bar{X}_c - \bar{X}_y)(\bar{X}_c - \bar{X}_y)[\bar{X}_y - E(\bar{X}_y)]}{\sum_c (X_i - X_y)^2}$$

But  $E(\bar{X}_y) = E\left[\frac{1}{n_y} \left(\sum_c X_i + \sum_{\text{om}} X_i\right)\right] = \frac{1}{n_y}(n_c \bar{X}_c + m_y \mu_x)$ ,

where  $\mu_x$  which is the population mean of  $X$ , is used to replace  $E(\bar{X}_{0,x})$ , since  $\bar{X}_{0,x}$  is not observed. Therefore,

$$E(\hat{\beta}_0) = \frac{\beta \sum_c (X_i - X_y)^2 + (n_c m_y / n_y)(\bar{X}_c - \bar{X}_y)(\bar{X}_c - \mu_x)}{\sum_c (X_i - X_y)^2} \neq \beta.$$

The conclusion, then, is that the zero order regression estimator of  $\beta$  is, in general, *biased*. The same is true of the zero order regression estimator of  $\alpha$ .

Before we leave the zero order regression method, let us consider some special cases. First, suppose that the values of  $X$  are all available and only some of the  $Y$ 's are missing. In this case,

$$n_x = n,$$

$$n_y = n_c,$$

$$m_y = 0,$$

$$\bar{X}_{0,x} = 0.$$

Then,

$$E(\hat{\beta}_0) = \beta \frac{\sum_c (X_i - X_y)^2}{\sum_c (X_i - X_y)^2},$$

Sec. 9-3] Estimation When Some Observations Are Missing

so that, unless  $\bar{X}_c = \bar{X}_y$ ,  $\hat{\beta}_0$  is still biased. Alternatively, suppose that the values of  $Y$  are all available but some of the  $X$ 's are missing. Then,

$$n_x = n_c,$$

$$n_y = n,$$

$$m_y = 0,$$

$$\bar{X}_x = \bar{X}_c,$$

and 
$$E(\hat{\beta}_0) = \frac{\beta \sum_c (X_i - X_c)^2}{\sum_c (X_i - X_c)^2} = \beta,$$

so that in this case the zero order regression estimator of  $\beta$  is unbiased. However, the variance of  $\hat{\beta}_0$ , conditional upon the observed  $X$ 's, in this case is

$$\text{Var}(\hat{\beta}_0) = E(\hat{\beta}_0 - \beta)^2 = E\left[\frac{\sum_c (X_i - \bar{X}_x)(\alpha - \bar{\alpha}_y)}{\sum_c (X_i - \bar{X}_x)^2}\right]^2 = \frac{\sigma^2}{\sum_c (X_i - \bar{X}_x)^2}$$

which is the same as the expression for  $\text{Var}(\hat{\beta}_0)$  given by (9.44). This means that we have nothing to gain in the way of efficiency by using  $\hat{\beta}_0$  instead of  $\hat{\beta}_x$ .

The zero order regression method of estimation is based on the idea of replacing each of the missing values of  $X$  by  $\bar{X}_x$ , and each of the missing values of  $Y$  by  $\bar{Y}_y$ . An alternative idea is to replace the missing values of  $X$  by a parameter  $\xi$ , and the missing values of  $Y$  by a parameter  $\eta$ . Since each of the missing values of  $X$  is replaced by the same parameter  $\xi$  and each of the missing values of  $Y$  is replaced by the same parameter  $\eta$ , this procedure brings in only two additional unknown parameters, regardless of sample size and the number of missing values. The regression coefficients  $\alpha$  and  $\beta$  can then be estimated simultaneously with  $\xi$  and  $\eta$ . This can be done by minimizing

$$\sum_c (Y_i - \alpha - \beta X_i)^2 + \sum_{\text{om}} (Y_i - \alpha - \beta \xi)^2 + \sum_{\text{om}} (\eta - \alpha - \beta X_i)^2$$

with respect to  $\alpha$ ,  $\beta$ ,  $\xi$ , and  $\eta$ . The resulting estimators, known as *modified zero order regression estimators*,<sup>6</sup> are

$$(9.51) \quad \hat{\beta}_m = \frac{\sum_c (X_i - X_c)(Y_i - Y_c)}{\sum_c (X_i - X_c)^2 + \sum_{\text{om}} (X_i - X_{0y})^2}$$

and

$$(9.52) \quad \hat{\alpha}_m = Y_c - \hat{\beta}_m \bar{X}_c.$$

<sup>6</sup> Ibid.

The estimators of  $\xi$  and  $\eta$ , which are of only incidental interest, are

$$\hat{\xi} = \frac{Y_{0x} - \hat{\alpha}_m}{\beta_m}$$

$$\hat{\eta} = \hat{\alpha}_m + \beta_m X_{0y}$$

and

Let us examine  $\hat{\alpha}_m$  and  $\beta_m$  for unbiasedness. For  $\beta_m$  we have

$$(9.51a) \quad \beta_m = \frac{\beta \sum (X_i - \bar{X}_0)^2 + \sum (X_i - \bar{X}_0)(e_i - \bar{e}_0)}{\sum (X_i - \bar{X}_0)^2 + \sum \frac{(X_i - \bar{X}_{0y})^2}{\sigma_y^2}}$$

and the mathematical expectation of  $\beta_m$ , conditional upon the observed  $X_i$ 's, is

$$E(\beta_m) = \frac{\beta \sum (X_i - \bar{X}_0)^2}{\sum (X_i - \bar{X}_0)^2 + \sum \frac{(X_i - \bar{X}_{0y})^2}{\sigma_y^2}} \neq \beta.$$

This means that the modified zero order regression estimator of  $\beta$  is, in general, *biased*. The same is true of the modified zero order regression estimator of  $\alpha$ . Again, let us examine some special cases. First, suppose that all of the values of  $X$  are available and only some of the  $Y$ 's are missing. In this case it is easy to show that formulas (9.51) and (9.52) remain the same, which means that we do not get any further ahead. Suppose, on the other hand, that all of the values of  $Y$  are available and only some of the  $X$ 's are missing. In this case formulas (9.51) and (9.52) become the same as (9.42) and (9.43). This means that the estimators  $\hat{\alpha}_m$  and  $\hat{\beta}_m$  are exactly equal to the ordinary least squares estimators based on complete pairs of observations only.

Summary

To sum up, when we deal with samples in which some pairs of observations are incomplete, the information contained in the incomplete pairs is of relatively little use when estimating the regression coefficients. When  $X$  is nonstochastic, the information contained in the pairs for which only the  $Y$ 's are given enables us to get an estimate of the loss of efficiency due to the fact that some of the  $X$ 's are missing. If this loss is substantial, it may be worthwhile to go to the trouble of attempting to recover the missing values of  $X$ , or to find some good approximations for them. When  $X$  is stochastic and we use either the zero order regression method or its modified version, we get estimators that are generally biased. If only values of  $X$  are missing, both methods will lead to unbiased estimates of  $\beta$ , but these will be no more efficient than the ordinary least squares estimates based on complete pairs only. One redeeming feature of the estimators of the regression coefficients obtained by the zero order regression method or its modified version is the fact that when the correlation between  $X$  and  $Y$  is low, the mean square error of these estimators is less than that of the ordinary least squares estimators based on complete pairs.\* Thus, under certain circumstances,

\* For a proof and an elaboration of this statement, see *ibid.*

Exercises

either one of the former methods may be preferable to estimation from complete pairs only.

EXERCISES

9-1. Assuming the "errors-in-variables" model, estimate the relationship between  $\log(Y/PZ)$  and  $\log(P/P)$  from the data for the furniture industry given in Table 9-1. Use the weighted regression method with  $\lambda = 2$ .

9-2. Suppose the income classes given in Table 9-2 in the text are combined as follows:

Income Class	Number of Observations ( $n_i$ )
Under 18	51
18 and under 22	44
22 and under 26	36
26 and under 30	26
30 and under 34	16
34 and over	8

Calculate the appropriate values of  $\bar{X}_i$  and  $\bar{Y}_i$  and use these to estimate the coefficients of

$$Y = \alpha + \beta X + \epsilon$$

and their standard errors. Compare your results with those based on the information as originally given in Table 9-2.

9-3. Provide a derivation of formula (9-47).

9-4. Consider the following observations on  $X$  (price of oranges) and  $Y$  (quantity of oranges sold):

$X$	$Y$
100	55
90	70
80	90
70	100
70	90
70	105
70	80
65	110
60	125
60	115
55	130
50	130
—	130
—	140

NOTES:

\* GNI per capita for Zimbabwe was estimated for Year 2002  
by World Development Indicators, The World Bank.

**Inflator:**

Wages are inflated, where the base year is not 2002, using consumer price index data reported in International Financial Statistics Online Service, International Monetary Fund, (<http://www.imf.org>, Downloaded July 9, 2004). The inflator rate is calculated by dividing the consumer price index for 2002 by the consumer price index for the year the wage rate was reported.

**Exchange rates:**

Exchange rates are expressed as foreign currency per one U.S. dollar. For the majority of the countries in this analysis, the exchange rates used are as reported in International Financial Statistics Online Service.

Wages for Austria, Belgium, Ireland and the Netherlands were reported in schillings, Belgian francs, pounds and guilders, respectively. These wages were converted to euros using the European Central Bank's conversion rates made effective on January 1, 1999 (<http://www.ecb.int>). No wage data used for these countries was reported before 1999.

**National Income:**

GNI per capita is reported in World Development Indicators, The World Bank, (Washington, DC: 2004). See World Development Indicators for further information.

World Development Indicators did not have a GNI per capita figure available for Zimbabwe so it supplied an estimate for 2002.

**Analysis:**

Regression based on ordinary least squares method.

## **Exhibit 2**

Report of Dr. Tapan K. Nayak, Ph.D.

Department of Commerce NME Wage Estimation

I Introduction

I have been retained by Grunfield, Desiderio, Lebowitz, Silverman and Klestadt LLP to provide an expert opinion on the appropriateness of the statistical regression used by the Department of Commerce (DOC) to estimate non-market-economy (NME) wage rates using market economies' per capita Gross National Income (GNI) and hourly labor rates. My professional background is included is appended to this report.

Regression analysis is a statistical methodology for relating a variable of interest, called the dependent (or response) variable, to one or more independent (or predictor) variables. The objective is to use the observed data to build a regression model, or prediction equation, which can then be used to describe, predict, or control the dependent variable on the basis of the independent variable(s). For example, a company may use regression analysis to model the relationship between sales and advertising expenditure, and then use that to decide how much they should spend for advertising.

A simple linear regression model relates a response variable (Y) and a single independent variable (X) by postulating that the mean value of the response variable,  $E(Y)$ , varies with the value of the independent variable following an unspecified linear pattern, i.e.,

$$E(Y) = \beta_0 + \beta_1 X.$$

The values of  $\beta_0$  and  $\beta_1$ , called the regression parameters, are estimated from the observed data. The actual value of Y would be different from the mean value  $E(Y)$ , and the data points would scatter around the regression line.

Many textbooks<sup>1</sup> present the specific methods and formulas for calculating the estimates, making predictions or model evaluation using a regression analysis.

## II. Application of Regression Analysis by DOC for Estimating NME Wage Rates

The Department of Commerce applies a regression analysis to estimate the wage rates of NME countries in antidumping duty investigations. For its proposed 2003 calculation, DOC modeled wage rate (Y) as a function of per capita GNI (X) using a simple linear regression model. In other words, DOC is using the observed relationship between GNI and wage rates in countries throughout the world to predict or estimate the wage rates in NME countries based on their respective GNI. The model parameters were estimated using hourly wages and per capita GNI of 52 market economy countries, and the method of ordinary least squares.<sup>2</sup> The wage rates for the NME country is then estimated by plugging-in its per capita GNI in the estimated regression equation, as described above.

## III. Bias Due to Arbitrary Data Selection by DOC

For estimating the regression equation, DOC used 52 countries whose wage data are available in the Yearbook of Labor Statistics 2004, published by the International Labor Organization, and whose GNI data was available from the 2005 World

---

<sup>1</sup> See, e.g., *Applied Linear Regression Models*, M. H. Kunter, C. J. Nachtsheim, and J. Neter, 2004, and *Applied Regression Analysis*, N. R. Draper, and H. Smith, 1998.

<sup>2</sup> See discussion below on ordinary least squares.

Development Indicators, published by the World Bank. However, the DOC ignored, without an explanation, many other countries whose GNI and wage data are also contained in the same sources.

As is well known, statistical estimates are not expected to be fully accurate, and they change from sample to sample. There are two aspects of estimation errors. One is “bias”, which is under or over-estimation “on the average.” The other one is variation of the estimates from sample to sample, which is measured technically by “standard error.” The total error is often measured by “mean squared error”, which is the sum of the squares of bias and standard error.

In general, the least square method (used by DOC) yields unbiased estimates (i.e., no systematic under or over-estimation) of the regression parameters provided that the assumed model is correct and that the data being utilized has been selected by a random sample. In addition, the standard errors decrease as sample size increases. The Department of Commerce also recognizes the fact that estimates based on a larger sample size are better, as evidenced by their statement: “In general, we believe that more data is better than less data, and that averaging of multiple data points (or regression analysis) should lead to more accurate results in valuing any factor production.”<sup>3</sup> Thus, one would expect more reliable estimates if more countries are included in the regression analysis for estimating NME wage rates.

Therefore, the most serious concern about the DOC analysis stems from the fact that the Department excluded 14 countries that have data that meets the Department’s selection criteria (i.e. countries with wage data that is not more than 6 years old, and for which there is consumer price indexes available) and whose data is available from the

---

<sup>3</sup> Notice of Final Rule Making, 62 Fed. Reg. 27296 at 27,367 (May 19, 1997).

same sources already being used by DOC. These market economy countries that the DOC excluded were not excluded randomly, as these countries have previously been excluded.<sup>4</sup> Given that the Department has not excluded these countries through a random sampling, the DOC results are biased.

More importantly, sampling of the available data is employed when dealing with large amounts of data points. Given the small size of the data set available for this regression analysis, random sampling will not result in a more accurate representation of the relationship between wages and GNI. Furthermore, given that the universe of available data would be complete with the inclusion of these 14 additional countries, there is no valid reason for the Department to exclude these countries' data. Thus, DOC should revise its 2003 wage rate estimates for NME countries by recalculating its regression equation including the 14 countries excluded for no reason.

---

<sup>4</sup> This has been the case for at least the last four years.

**Book Reviews:**

Review of *Statistical Significance: Rationale, Validity and Utility* by Siu L. Chow. *Technometrics*, (1998), 40, 161-162.

Review of *Theory of Point Estimation (2nd ed.)* by E.L. Lehmann and George Casella. *Journal of Statistical Planning and Inference*, (2001), 93, 323-324.

**Ph. D. Students Supervised:**

Mary C. Christman. Thesis: "On Estimation of the Number of Classes in a Population" (1993).

Christopher L. Moriarity. (Co-advisor) Thesis: "Statistical Properties of Statistical Matching" (2001).

Abeer El-Baz. Thesis: "Some Contributions to Statistical Prediction Theory" (2004).

**Professional Service:**

Associate Editor, *Communications in Statistics - Theory and Methods*, 2002-present.

Associate Editor, *Communications in Statistics - Simulation and Computation*, 2002-present.

Guest Editor of *Sankhya, Ser. A, Vol. 64(2)*, (2002); a special issue in honor of Professor C.R. Rao.

Reviewer, *Mathematical Reviews*, 1995 - present.

Member, Review Panel for evaluating research grant proposals submitted to Bureau of Transportation Statistics (2001).

Organizing Committee member of the international conference "Statistics: Reflections on the Past, Visions for the Future" (in honor of Professor C.R. Rao's 80th birthday) held in San Antonio, Texas, during March 16 - 20, 2000.

Methodology Program Chair, Washington Statistical Society, 1991-1992.

Methodology Section Chair, Washington Statistical Society, 1992-1993.

Treasurer, International Indian Statistical Association, 1997-1999.

Reviewer of research proposals for agencies such as NSF, EPA.

**University Service:**

Member, Faculty Senate Committee on Faculty Development and Support, 1993-1994.

Member, Junior Scholar Research Incentive Award Committee, 1994-1995.

Member, Dean's Council, 2000-2003.

**Departmental Service:**

Chairman, 2001 - present.

Ph. D. Committee, Chair, since 1991; member, since 1983.

Tenure and Promotion Review Committee, Chair, 1996-1997; member, 1992-1993, & 1995-1996.

Departmental representative to the University (Gelman) Library, 1985-1990.

Faculty Search Committee, 1991-1992, 1993-1994, 1996-1997, 1998-1999.

Served as a reader or examiner of a dozen or more Ph. D. dissertations.

**Research Grants:**

Junior Scholar Research Incentive Program Award, George Washington University, 1986.

University Research Grant, George Washington University, 1988.

IPA (Intergovernmental Personnel Act) assignment. Funded by National Agricultural Statistics Service, July 1997 - August 1998

Co-PI on a cooperative research agreement with the Office of Waters of the US Environmental Protection Agency, 1999-2001.

Statistical Methods in Marketing Research. (PI), Capital One Services, Inc., 2004-2005.
